Therefore, to improve system efficiency and power factor, capacitor banks are used, which lessen the system"s inductive effect by reducing lag in current. This, ultimately, raises the power factor. So, we can say that capacitor banks reduce power losses by improving or correcting the power factor. They are commonly used for these three reasons:

1. Static Capacitor. We know that most industries and power system loads are inductive, which causes a decrease in the system power factor due to lagging current (see disadvantages of low power factor). To improve the power factor, static capacitors are connected in parallel with these devices operated on low power

Examples of capacitive loads are capacitors, variable or fixed capacitor banks, motor starting capacitors, generators, and synchronous motors. Power factor correction (PFC) is usually achieved by adding capacitive load to offset the inductive load present in the power system. The power factor of the power system is

Now if we connect the suitably sized and designed (already discussed in part1 to 3) capacitor bank in parallel to the loads connected to DG and improve the average overall load power factor from 0.7 to 0.85 then for the same percentage loading of 85.7% that is 857kVA the active power that can be drawn is = $857 \times 0.85 = 728.45$ kWHence one can see the moment ...

By adding capacitive banks, you can add additional load to a system without altering the apparent power. Banks can also be used in a direct-current (DC) power supply to increase the ripple-current capacity of the power supply or to increase the overall amount of stored energy.

By mitigating power losses through power factor correction, regulating voltage in substations, and improving transient responses, capacitor banks contribute significantly to the reliability of power supply.
