condition. Transient analysis is the analysis of the circuits during the time it changes from one steady state condition to another steady state condition. Transient analysis will reveal how the currents and voltages are changing during the transient period. To get such time responses, the mathematical models should

The transient recovery voltage or TRV is present immediately after the interruption of the current. When the TRV oscillation has damped out, the power frequency-recovery voltage is active.

Power and Energy Series 67 Multicore technology has brought about the reexamination of traditional power system electromagnetic transient simulation methods. The technological penetration of this advancement in power system simulation is not noticeable, but its demand is growing in importance in anticipation of the many-core shift.

After a time span of three times the damping time constant  $t$  ( $t = 2L/R$ ), only 5 percent of the initial amplitude of the transient waveform is present in the network. It is not necessary that after every change of state, such as after a switching action, transient oscillations occur in a network.
