A high-voltage energy storage system (ESS) offers a short-term alternative to grid power, enabling consumers to avoid expensive peak power charges or supplement inadequate grid power during high-demand periods. These systems address the increasing gap between energy availability and demand due to the expansion of wind and solar energy generation.

To reduce the safety risk associated with large battery systems, it is imperative to consider and test the safety at all levels, from the cell level through module and battery level and all the way to the system level, to ensure that all the safety controls of the system work as expected.

Stretchable batteries, which store energy through redox reactions, are widely considered as promising energy storage devices for wearable applications because of their high energy density, low discharge rate, good long-term stability, and lack of memory effect.

The battery management system (BMS) is the main safeguard of a battery system for electric propulsion and machine electrification. It is tasked to ensure reliable and safe operation of battery cells connected to provide high currents at high voltage levels. The battery never reaches the float (or storage) stage. The float (or storage) stage follows the absorption stage. During this stage, the charge voltage drops to 13.5V and the battery can be considered full. If the charger never enters this stage, it might be a sign that the absorption stage has not been completed (see previous point).

The narrow cell voltage results in a limited energy density for devices operated in aqueous-based electrolytes since the energy in a supercapacitor is proportional to the square of the cell voltage, as shown by Eq. (1): (1) $E = \frac{1}{2} C V^2$, where E is the energy (J), C is the capacitance (F) and V is the cell voltage (V).
