Boiling water is also used for control purposes because steam bubbles are not a very good moderator compared to water and thus the fission reaction is attenuated. The water pressure is 7 MPa and its temperature is about 280 °C. The steam generated inside the reactor is dried and supplied directly to a turbine. This is a single-circuit power plant.

The storage volume ranges from 2 to 4 ft³/ton-hour for ice systems, compared to 15 ft³/ton-hour for a chilled water. The application for energy storage systems varies by industry, and can include district cooling, data centers, combustion ...
