Energy Storage: The insulator keeps the charges apart even after the power source is disconnected. The capacitor functions as a little battery thanks to the electrical energy that is stored inside the electric field. Discharging the Energy: The capacitor's stored energy wants to go back and forth when it is connected to a circuit. A current ...

You have two capacitors that you wish to use in an energy-storage device: $C_1 = 1.00 \text{ mF}$ and $C_2 = 9.00 \text{ mF}$. How much energy is stored in capacitor C_1 if it has charge $4.50 \times 10^{-4} \text{ C}$? Express your answer with the appropriate units. How much energy is stored in capacitor C_2 if it has charge $4.50 \times 10^{-4} \text{ C}$? Express your answer with the appropriate units.

These two distinct energy storage mechanisms are represented in electric circuits by two ideal circuit elements: the ideal capacitor and the ideal inductor, which approximate the behavior of actual discrete capacitors and inductors. They also approximate the bulk properties of capacitance and inductance that are present in any physical system.
