power flows in the system. The power system is a large interconnected system, where various buses are connected by transmission lines. At any bus, complex power is injected into the bus by the generators and complex power is drawn by the loads. Of course at any bus, either one of them may not be present.

While analog simulation techniques have a place in the study of system dynamics, capability and exhibility have made digital simulation the primary method for analysis. There are several main divisions in the study of power system dynam-ics and stability . F. P. deMello classi ed dynamic processes into three categories:

During the power system analysis, it is a usual practice to represent current, voltage, impedance, power, etc., of an electric power system in per unit or percentage of the base or reference value of the respective quantities. The numerical per unit (pu) value of any quantity is its ratio to a chosen base value of the same dimension.
