The software uses on- and off-design modes to complete this analysis. In on-design, the electrical power system components are sized (to estimate system mass, loss, and efficiency). In off-design, the system's performance (such as loss, and efficiency) is calculated at points in the power system's operating range.

oModular structure enabling simulations of power systems with arbitrary topology in transient or steady-state conditions. oParameterization of components and modularity enable to build complex sub-models of new components. oAnalysis of the dynamic behavior of complex electrical systems comprising electrical machines, power electronics

Power System Harmonics is a real point of concern for Electrical Engineers. In power systems, non-linear loads are permanently connected, unlike transients and other distortions are produced.

Basic power system theory states that all three phases of a power system should be equally balanced to optimise the system and prevent excessive heating and neutral currents. This is problematic for DNOs, hence why the P29 rules exist. An unbalanced power system can cause G59 protection relays to trip due to a vector shift and phase unbalance.
