

In a weak energy environment, the output power of a miniature piezoelectric energy harvester is typically less than 10mW. Due to the weak diode current, the rectifier diode of traditional power management circuit in micro-power energy harvester has a high on-resistance and large power consumption, causing a low charging power. That energy can also be calculated from the expression $\frac{1}{2} L I^2$ (note that L in Figure 4 is N times larger, and I is N times smaller). Because the circuit of Figure 1c delivers less energy per pulse, the ripple is N times smaller. Thus, a transformer not only leverages the output voltage up; it also leverages the output ripple down.
