The energy stored in the magnetic field of an inductor can be calculated as. $W = \frac{1}{2} L I^2$ (1) where . W = energy stored (joules, J) L = inductance (henrys, H) I = current (amps, A) Example - Energy Stored in an Inductor. The energy stored in an inductor with inductance 10 H with current 5 A can be calculated as. $W = \frac{1}{2} (10 \text{ H}) (5 \text{ A})^2$

Resistance of the coil: The resistance of the coil, while not directly present in the formula, influences the current through the inductor. A high resistance coil will allow less current to flow, thus reducing the energy stored. Hence, resistance indirectly affects the energy stored in an inductor.

Inductance of the coil: The amount of energy stored in an inductor is directly proportional to its inductance. Higher the inductance, higher will be the energy stored. Current flowing through the coil: The energy stored is directly proportional to the square of the current flowing through the inductor.

This is highlighted as the area under the power curve in Figure 2. The energy in the inductor can be found using the following equation: $w = \frac{1}{2} L i^2$ (2) Where i is the current (amperes), L is inductance (Henry), and w is the stored energy (joules). Increasing the number of coil turns in an inductor increases its inductance. As the energy stored in an inductor is directly proportional to its inductance, this means the energy stored would also increase.

Since inductance pertains to energy storage, the question is really what fraction of the energy is stored in a field that is well-described by this approximation, as opposed to energy stored in the "fringing field" close to the ends of the coil.

Mutual inductance is the effect of Faraday's law of induction for one device upon another, such as the primary coil in transmitting energy to the secondary in a transformer. See Figure, where simple coils induce emfs in one another.
