Many electronic devices use inductors for energy storage and transfer because they allow the stored energy to be released back into the circuit when the current changes.

Thus, the power delivered to the inductor $p = v \cdot i$ is also zero, which means that the rate of energy storage is zero as well. Therefore, the energy is only stored inside the inductor before its current reaches its maximum steady-state value, I_m . After the current becomes constant, the energy within the magnetic becomes constant as well.
