Energy is stored in a magnetic field. It takes time to build up energy, and it also takes time to deplete energy; hence, there is an opposition to rapid change. In an inductor, the magnetic field is directly proportional to current and to the inductance of the device. It can be shown that the energy stored in an inductor (E_{ind}) is given by

An inductor, physically, is simply a coil of wire and is an energy storage device that stores that energy in the electric fields created by current that flows through those coiled wires. But this coil of wire can be packaged in a myriad of ways so that an inductor can look like practically anything.

Some of the available energy from the source is evidently being diverted away from its usual task of pushing

- Applications: Capacitors are used in applications such as energy storage, smoothing power supplies, filtering signals, coupling and decoupling, timing circuits, and as part of oscillators. Differences: - Energy Storage: Inductors store energy in magnetic fields, while capacitors store energy in electric fields.

We can now determine the energy within the inductor by integrating this power over time: $[U_{\text{inductor}}] = \inf Pdt = \inf \{dI\}\{dI\}\{dI\}\{dI\}\} = \inf IdI = \{I\}\{2\} LI^2\}$ There is clearly a resemblance of this energy to that of a charged capacitor, though the parallels are not immediately obvious.

Connect the inductor coil in series with the resistor. In series means the current passes through the coil one after the other. Start setting up a circuit by placing the coil and resistor next to each other. Make sure they have 1 terminal touching.
