Pumped hydroelectric energy storage stores energy in the form of potential energy of water that is pumped from a lower reservoir to a higher level reservoir. In this type of system, low cost electric power (electricity in off-peak time) is used to run the pumps to raise the water from the lower reservoir to the upper one.

Pumped storage hydropower represents the bulk of the United States" current energy storage capacity: 23 gigawatts (GW) of the 24-GW national total (Denholm et al. 2021). This capacity was largely built between 1960 and 1990. PSH is a mature and proven method of energy storage with competitive round-trip efficiency and long life spans.

Pumped hydro storage is a method of storing energy by using excess electricity to pump water uphill to a reservoir during low demand and then releasing it back down to generate electricity when needed. This technique helps balance energy supply and demand, making it a critical part of renewable energy systems and grid management. It leverages gravitational potential energy, ...

The relatively low energy density of pumped storage systems requires either large flows and/or large differences in height between reservoirs. The only way to store a significant amount of energy is by having a large body of water located relatively near, but as high as possible above, a second body of water.
