

Organic phase change materials (PCMs) play an important role in heat energy storage, but they are also limited by the leakage problem in the process of phase change. Herein, shape-stabilized composite PCMs (ssPCMs) are successfully obtained by impregnating paraffin (PA) into the polymethylsilsesquioxane (PMSQ) aerogels. Due to abundant porosity, light ...

With this arrangement, the light-sensitive component alters the thermal properties of the other component, which stores and releases its energy. The hybrid material melts when heated, and after being exposed to ultraviolet light, it stays melted even when cooled back down.

It is obvious that the melting point of the new binary eutectic salt mixture is much lower than that of conventional solar salt @220 °C and HITEC salt@142 °C. Decrease of melting point enhances the thermal energy storage capacity due to the increase in the working temperature range.

Usually the change occurs when adding or removing heat at a particular temperature, known as the melting point or the boiling point of the substance. The melting point is the temperature at which the substance goes from a solid to a liquid (or from a liquid to a solid).

Additionally, visible light in the solar spectrum hinders the storage of UV energy using conventional azo-based photoswitchable materials because the visible light converts the charged cis isomers back to uncharged trans isomers, as illustrated in Figure 3 A. Due to visible light-induced back isomerization, broad-spectrum sunlight irradiation ...

meant that the PEG could not reach its melting point and realize the solar energy storage. Thus, the composite PCMs based on HGA had better performance in light-to-heat energy conversion. The light-to-heat and energy storage efficiency of the composite PCMs can be calculated by using photothermal calculation [36]. The energy
