Two-element circuits and uncoupled RLC resonators. RLC resonators typically consist of a resistor R, inductor L, and capacitor C connected in series or parallel, as illustrated in Figure 3.5.1. In a series RL circuit, the resistor and the inductor are connected in a series configuration, meaning the current flowing through the circuit passes through both components sequentially. The inductor in the circuit generates a magnetic field that stores energy in the form of an electromagnetic field. The resistor, on the other hand, resists the flow of current and ...

In addition, we can use the inductor's energy storage and return capability to great advantage in our electronic circuits. Boost Converters, which are used to increase a DC voltage, say from a 9V battery at the input to the 100V or more needed to drive a vacuum fluorescent display, use an inductor's ability to store and return energy to ...

Capacitors in series combine like inductors in parallel, while capacitors in parallel combine like inductors in series. Another example of duality is seen in the DC behavior of capacitors and inductors. In a DC circuit, a capacitor acts like an open circuit, while an inductor acts like a short-circuit. Energy Storage in Inductors

An inductor carrying a current has energy stored in it. Rate of transfer of energy into L: Total energy U supplied while the current increases from zero to I: Energy supplied to inductor during dt:  $dU = P dt = L i di$
