Sensible heat storage, by its definition, means that thermal energy (heat or cold) is stored in the form of sensible heat in the storage medium, which does not undergo any phase change during charging or discharging process. The single process involved is the temperature variation of the storage medium within one phase.

9) Sensible Heat: The heat used to change the temperature of the air. Sensible heat will always cause a change in the temperature of the substance. 10) Latent heat: Latent heat is the heat energy involved in the phase change of water. The heat will only change the structure or phase of the material without change to temperature. Psychrometric Chart

Thermal energy may be stored as sensible heat or latent heat. Sensible heat storage systems utilize the heat capacity and the change in temperature of the material during the process of charging or discharging - temperature of the storage material rises when energy is absorbed and drops when energy is withdrawn.

storage systems based on sensible heat storage. This is not generally true; for most PCMs, the phase change enthalpy Δh_{pc} corresponds to the change in sensible heat with a temperature change between 100-200K, so the storage density of sensible heat storage systems with large operating temperature ranges can be higher. An

Sensible heat storage (SHS) is by far the most common method for heat storage [8]. It is the simplest and

easiest form of heat storage technology [12]. Sensible heat is the heat exchanged by a system that does not change its phase but changes the temperature of a storage medium. The temperature changes linearly in relation to the stored heat.

Sensible heat thermal energy storage materials store heat energy in their specific heat capacity (C_p). The thermal energy stored by sensible heat can be expressed as $Q = m \cdot C_p \cdot \Delta T$ where m is the mass (kg), C_p is the specific heat capacity ($\text{kJ} \cdot \text{kg}^{-1} \cdot \text{K}^{-1}$) and ΔT is the raise in temperature during charging process.

The basic principle is that heat is absorbed by storage materials using conventional heat transfer phenomena either conduction, convection or radiations, which also releases heat during night with same heat transfer phenomena. The sensible heat storage system includes hot as well as cold-water tanks and underground storage systems.

very low volumetric heat capacity and are therefore not used for sensible heat or cold storage. Sensible heat storage is by far the most common method for heat storage. Hot water heat storages are used for domestic heating and domestic hot water in every household. In recent years, heat storage in the ground has also been applied more and more.

Where (\overline{C}_p) is the average specific heat of the storage material within the temperature range. Note that constant values of density ρ ($\text{kg} \cdot \text{m}^{-3}$) are considered for the majority of storage materials applied in buildings. For packed bed or porous medium used for thermal energy storage, however, the porosity of the material should also be taken into account.

Heat storage techniques are going to be discussed in the following sections, along with hybrid heat storage systems that combine sensible and latent heat storage methods. In a number of sources, heat storage methods are divided into three categories: sensible, latent, and thermochemical.

2.1 Sensible-Thermal Storage. Sensible storage of thermal energy requires a perceptible change in temperature. A storage medium is heated or cooled. The quantity of energy stored is determined by the specific thermal capacity (c_p -value) of the material. What is thermal energy storage? Thermal energy storage means heating or cooling a medium to use the energy when needed later. In its simplest form, this could mean using a water tank for heat storage, where the water is heated at times when there is a lot of energy, and the energy is then stored in the water for use when energy is less plentiful.

Some parameters must be met for a thermal energy storage system to be effective. The common sensible heat storage materials must have a high energy density (high density and specific heat) and high thermal conductivity (often more significant than 0.3 W/m K for residential applications) .
