Thermal plants equipped with carbon capture, utilisation and storage technologies are also expected to play an important role in providing flexibility. Plant operators can run them in a flexible manner to accommodate short-term variations, very much like unabated thermal power plants today. These technologies have various effects on plant operation.

Other sources of thermal energy for storage include heat or cold produced with heat pumps from off-peak, lower cost electric power, a practice called peak shaving; heat from combined heat and power (CHP) power

plants; heat produced by renewable electrical energy that exceeds grid demand and waste heat from industrial processes.

The combined-heat-and-power (CHP) plants play a central role in many heat-intensive energy systems, contributing for example about 10% electricity and 70% district heat in Sweden. This paper considers a proposed system integrating a high-temperature thermal storage into a biomass-fueled CHP plant.

Particle thermal energy storage is a less energy dense form of storage, but is very inexpensive (\$2-\$4 per kWh of thermal energy at a 900°C charge-to-discharge temperature difference).
