There are scenarios where the peak power demand in the power grid may exceed the maximum storage capacity of the supercapacitor array; necessitating power filtration to safeguard energy storage. Conversely, during energy extraction from the supercapacitor array, the voltage gradually decreases due to the inherent properties of the supercapacitors.

Energy Density vs. Power Density in Energy Storage . Supercapacitors are best in situations that benefit from short bursts of energy and rapid charge/discharge cycles. They excel in power density, absorbing energy in short bursts, but they have lower energy density compared to batteries (Figure 1). They can't store as much energy for long ...

Low Energy Density: Compared to other forms of energy storage like batteries, capacitors store less energy per unit of volume or mass, making them less suitable for long-duration energy storage. **High Self-Discharge:** Capacitors tend to lose their stored energy relatively quickly when not in use, known as self-discharge.

In a power backup or holdup system, the energy storage medium can make up a significant percentage of the total bill of materials (BOM) cost, and often occupies the most volume. The key to optimizing a solution is a careful selection of components so that holdup times are met, but the system is not overdesigned.

Double Layer Capacitors. Many energy storage modules will use electric double layer capacitors, often referred to as super capacitors. Super capacitors use a liquid electrolyte and charcoal to form what is known as an electrical double layer. This greatly increases the capacitance. Capacitors with large Farad rating and small size can be obtained.

For high-energy storage with capacitors in series, some safety considerations must be applied to ensure one capacitor failing and leaking current does not apply too much voltage to the other series capacitors. Series connection is also sometimes used to adapt polarized electrolytic capacitors for bipolar AC use.
