

The principle behind Flyback converters is based on the storage of energy in the inductor during the charging, or the "on period," ton, and the discharge of the energy to the load during the "off period," toff. There are four basic types that are the most common, energy storage, inductor type converter circuits. 1. Step down, or buck converter. 2.

Due to the high output voltage of the PFC stage, a moderate amount of energy can be stored in the PFC output capacitance. This energy can be used by the product to ride through PFC DC/DC

How Does an Inductor Store Energy? Inductors store energy in the form of a magnetic field. The inductor generates a magnetic field that stores energy as current passes through the wire coil. 4. Interleaved PFC: The term " interleaved PFC" refers to a configuration in which numerous PFC circuits are functioning in parallel but are not in phase with one another. This interleaving helps to reduce ripple current, which in turn makes it possible to use capacitors and inductors that are smaller and less expensive.

Regardless of the regulatory requirements or the behavior of any particular circuit, the goal of PFC is to make the load behave as much like a pure resistance as possible: if the mains voltage waveform is a sinusoid then the load current should also be a sinusoid (with as close to 0° phase displacement as possible).
